3. K and  $\bar{K}$  cannot be set to V<sub>REF</sub> voltage.

## Background

Common I/O SRAMs, from a system architecture point of view, are attractive in read dominated or block transfer applications. Therefore, the SigmaDDR-II+ SRAM interface and truth table are optimized for burst reads and writes. Common I/O SRAMs are unpopular in applications where alternating reads and writes are needed because bus turnaround delays can cut high speed Common I/O SRAM data bandwidth in half.

## Burst Operations

Read and write operations are "Burst" operations. In every case where a read or write command is accepted by the SRAM, it will respond by issuing or accepting two beats of data, executing a data transfer on subsequent rising edges of  $K$  and  $\bar{K}$ , as illustrated in the timing diagrams. This means that it is possible to load new addresses every  $K$  clock cycle. Addresses can be loaded less often, if intervening deselect cycles are inserted.

## Deselect Cycles

Chip Deselect commands are pipelined to the same degree as read commands. This means that if a deselect command is applied to the SRAM on the next cycle after a read command captured by the SRAM, the device will complete the two beat read data transfer and then execute the deselect command, returning the output drivers to High-Z. A high on the  $\bar{LD}$  pin prevents the RAM from loading read or write command inputs and puts the RAM into deselect mode as soon as it completes all outstanding burst transfer operations.

## SigmaDDR-II+ Burst of 2 SRAM Read Cycles

The SRAM executes pipelined reads. The status of the Address,  $\bar{LD}$  and  $R/\bar{W}$  pins are evaluated on the rising edge of  $K$ . The read command ( $\bar{LD}$  low and  $R/\bar{W}$  high) is clocked into the SRAM by a rising edge of  $K$ .

## SigmaDDR-II+ Burst of 2 SRAM Write Cycles

The status of the Address,  $\bar{LD}$  and  $R/\bar{W}$  pins are evaluated on the rising edge of  $K$ . The SRAM executes "late write" data transfers. Data in is due at the device inputs on the rising edge of  $K$  following the rising edge of  $K$  clock used to clock in the write command ( $\bar{LD}$  and  $R/\bar{W}$  low) and the write address. To complete the remaining beat of the burst of two write transfer, the SRAM captures data in on the next rising edge of  $\bar{K}$ , for a total of two transfers per address load.

## Special Functions

### Byte Write and Nybble Write Control

Byte Write Enable pins are sampled at the same time that Data In is sampled. A high on the Byte Write Enable pin associated with a particular byte (e.g.,  $\bar{BW}0$  controls D0–D8 inputs) will inhibit the storage of that particular byte, leaving whatever data may be stored at the current address at that byte location undisturbed. Any or all of the Byte Write Enable pins may be driven High or Low during the data in sample times in a write sequence.

Each write enable command and write address loaded into the RAM provides the base address for a 2-beat data transfer. The x18 version of the RAM, for example, may write 36 bits in association with each address loaded. Any 9-bit byte may be masked in any write sequence.

Nybble Write (4-bit) control is implemented on the 8-bit-wide version of the device. For the x8 version of the device, "Nybble Write Enable" and " $\bar{NW}x$ " may be substituted in all the discussion above.

## Resulting Write Operation

Byte 1 D0–D8	Byte 2 D9–D17	Byte 3 D0–D8	Byte 4 D9–D17
Written	Unchanged	Unchanged	Written
Beat 1		Beat 2	

### Example x18 RAM Write Sequence using Byte Write Enables

Data In Sample Time	$\overline{BW0}$	$\overline{BW1}$	D0–D8	D9–D17
Beat 1	0	1	Data In	Don't Care
Beat 2	1	0	Don't Care	Data In

### FLXDrive-II Output Driver Impedance Control

HSTL I/O SigmaDDR-II+ SRAMs are supplied with programmable impedance output drivers. The ZQ pin must be connected to  $V_{SS}$  via an external resistor, RQ, to allow the SRAM to monitor and adjust its output driver impedance. The value of RQ must be 5X the value of the desired RAM output impedance. The allowable range of RQ to guarantee impedance matching continuously is between 175 $\Omega$  and 350 $\Omega$ . Periodic readjustment of the output driver impedance is necessary as the impedance is affected by drifts in supply voltage and temperature. The SRAM's output impedance circuitry compensates for drifts in supply voltage and temperature. A clock cycle counter periodically triggers an impedance evaluation, resets and counts again. Each impedance evaluation may move the output driver impedance level one step at a time towards the optimum level. The output driver is implemented with discrete binary weighted impedance steps.

### Input Termination Impedance Control

These SigmaDDR-II+ SRAMs are supplied with programmable input termination on Data (DQ), Byte Write ( $\overline{BW}$ ), and Clock (K,  $\overline{K}$ ) input receivers. Input termination can be enabled or disabled via the ODT pin (6R). When the ODT pin is tied Low (or left floating—the pin has a small pull-down resistor), input termination is disabled. When the ODT pin is tied High, input termination is enabled. Termination impedance is programmed via the same RQ resistor (connected between the ZQ pin and  $V_{SS}$ ) used to program output driver impedance, and is nominally  $RQ \cdot 0.6$  Thevenin-equivalent when RQ is between 175 $\Omega$  and 250 $\Omega$ . Periodic readjustment of the termination impedance occurs to compensate for drifts in supply voltage and temperature, in the same manner as for driver impedance (see above).

#### Notes:

- When ODT = 1, Byte Write ( $\overline{BW}$ ), and Clock (K,  $\overline{K}$ ) input termination is always enabled. Consequently,  $\overline{BW}$ , K,  $\overline{K}$  inputs should always be driven High or Low; they should never be tri-stated (i.e., in a High-Z state). If the inputs are tri-stated, the input termination will pull the signal to  $V_{DDQ}/2$  (i.e., to the switch point of the diff-amp receiver), which could cause the receiver to enter a meta-stable state, resulting in the receiver consuming more power than it normally would. This could result in the device's operating currents being higher.
- When ODT = 1, DQ input termination is enabled during Write and NOP operations, and disabled during Read operations. Specifically, DQ input termination is disabled 0.5 cycles before the SRAM enables its DQ drivers and starts driving valid Read Data, and remains disabled until 0.5 cycles after the SRAM stops driving valid Read Data and disables its DQ drivers; DQ input termination is enabled at all other times. Consequently, the SRAM Controller should disable its DQ input termination, enable its DQ drivers, and drive DQ inputs (High or Low) during Write and NOP operations. And, it should enable its DQ input termination and disable its DQ drivers during Read operations. Care should be taken during Write or NOP  $\rightarrow$  Read transitions, and during Read  $\rightarrow$  NOP transitions, to minimize the time during which one device (SRAM or SRAM Controller) has enabled its DQ input termination while the other device has not yet enabled its DQ driver. Otherwise, the input termination will pull the signal to  $V_{DDQ}/2$  (i.e., to the switch point of the diff-amp receiver), which could cause the receiver to enter a meta-stable state, resulting in the receiver consuming more power than it normally would. This could result in the device's operating currents being higher.

## Common I/O SigmaDDR-II+ Burst of 2 SRAM Truth Table

$K_n$	$\overline{LD}$	$R/\overline{W}$	DQ		Operation
			A + 0	A + 1	
↑	1	X	Hi-Z / *	Hi-Z / *	Deselect
↑	0	0	$D@K_{n+1}$	$D@K_{n+1}$	Write
↑	0	1	$Q@K_{n+2}$	$Q@K_{n+3}$	Read

**Notes:**

1. "1" = input "high"; "0" = input "low"; "V" = input "valid"; "X" = input "don't care".
2. D1 and D2 indicate the first and second pieces of Write Data transferred during Write operations.
3. Q1 and Q2 indicate the first and second pieces of Read Data transferred during Read operations.
4. When On-Die Termination is disabled (ODT = 0), DQ drivers are disabled (i.e., DQ pins are tri-stated) for one cycle in response to NOP and Write commands, 2.5 cycles after the command is sampled.
5. When On-Die Termination is enabled (ODT = 1), DQ drivers are disabled for one cycle in response to NOP and Write commands, 2.5 cycles after the command is sampled. The state of the DQ pins during that time (denoted by "\*" in the table above) is determined by the state of the DQ input termination. See the Input Termination Impedance Control section for more information.

#### Operating Temperature

Parameter	Symbol	Min.	Typ.	Max.	Unit
Junction Temperature (Commercial Range Versions)	$T_J$	0	25	85	$^{\circ}$ C
Junction Temperature (Industrial Range Versions)*	$T_J$	-40	25	100	$^{\circ}$ C

#### Note:

\* The part numbers of Industrial Temperature Range versions end with the character "I". Unless otherwise noted, all performance specifications quoted are evaluated for worst case in the temperature range marked on the device.

## Thermal Impedance

Package	Test PCB Substrate	$\theta_{JA}$ (C°/W) Airflow = 0 m/s	$\theta_{JA}$ (C°/W) Airflow = 1 m/s	$\theta_{JA}$ (C°/W) Airflow = 2 m/s	$\theta_{JB}$ (C°/W)	$\theta_{JC}$ (C°/W)
165 BGA	4-layer	16.4	13.4	12.4	8.6	1.2

### Notes:

1. Thermal Impedance data is based on a number of samples from multiple lots and should be viewed as a typical number.
2. Please refer to JEDEC standard JESD51-6.
3. The characteristics of the test fixture PCB influence reported thermal characteristics of the device. Be advised that a good thermal path to the PCB can result in cooling or heating of the RAM depending on PCB temperature.

## HSTL I/O DC Input Characteristics

Parameter	Symbol	Min	Max	Units	Notes
Input Reference Voltage	$V_{REF}$	$V_{DDQ}/2 - 0.05$	$V_{DDQ}/2 + 0.05$	V	—
Input High Voltage	$V_{IH1}$	$V_{REF} + 0.1$	$V_{DDQ} + 0.3$	V	1
Input Low Voltage	$V_{IL1}$	-0.3	$V_{REF} - 0.1$	V	1
Input High Voltage	$V_{IH2}$	$0.7 * V_{DDQ}$	$V_{DDQ} + 0.3$	V	2,3
Input Low Voltage	$V_{IL2}$	-0.3	$0.3 * V_{DDQ}$	V	2,3

### Notes:

1. Parameters apply to  $\overline{K}$ ,  $\overline{K}$ , SA, DQ,  $\overline{R/W}$ ,  $\overline{B/W}$ ,  $\overline{LD}$  during normal operation and JTAG boundary scan testing.
2. Parameters apply to Doff, ODT during normal operation and JTAG boundary scan testing.
3. Parameters apply to ZQ during JTAG boundary scan testing only.

## HSTL I/O AC Input Characteristics

Parameter	Symbol	Min	Max	Units	Notes
Input Reference Voltage	$V_{REF}$	$V_{DDQ}/2 - 0.08$	$V_{DDQ}/2 + 0.08$	V	—
Input High Voltage	$V_{IH1}$	$V_{REF} + 0.2$	$V_{DDQ} + 0.5$	V	1,2,3
Input Low Voltage	$V_{IL1}$	-0.5	$V_{REF} - 0.2$	V	1,2,3
Input High Voltage	$V_{IH2}$	$V_{DDQ} - 0.2$	$V_{DDQ} + 0.5$	V	4,5
Input Low Voltage	$V_{IL2}$	-0.5	0.2	V	4,5

### Notes:

1.  $V_{IH(MAX)}$  and  $V_{IL(MIN)}$  apply for pulse widths less than one-quarter of the cycle time.
2. Input rise and fall times must be a minimum of 1 V/ns, and within 10% of each other.
3. Parameters apply to  $\overline{K}$ ,  $\overline{K}$ , SA, DQ,  $\overline{R/W}$ ,  $\overline{B/W}$ ,  $\overline{LD}$  during normal operation and JTAG boundary scan testing.
4. Parameters apply to Doff, ODT during normal operation and JTAG boundary scan testing.
5. Parameters apply to ZQ during JTAG boundary scan testing only.

## Capacitance

( $T_A = 25^\circ\text{C}$ ,  $f = 1\text{ MHz}$ ,  $V_{DD} = 1.8\text{ V}$ )

Parameter	Symbol	Test conditions	Typ.	Max.	Unit
Input Capacitance	$C_{IN}$	$V_{IN} = 0\text{ V}$	4	5	pF
Output Capacitance	$C_{OUT}$	$V_{OUT} = 0\text{ V}$	6	7	pF
Clock Capacitance	$C_{CLK}$	$V_{IN} = 0\text{ V}$	5	6	pF

**Note:**

This parameter is sample tested.

## AC Test Conditions

Parameter	Conditions
Input high level	1.25 V
Input low level	0.25 V
Max. input slew rate	2 V/ns
Input reference level	0.75 V
Output reference level	$V_{DDQ}/2$

**Note:**

Test conditions as specified with output loading as shown unless otherwise noted.

**HSTL I/O Output Driver DC Electrical Characteristics**

Parameter	Symbol	Min.	Max.	Units	Notes
Output High Voltage	$V_{OH1}$	$V_{DDQ}/2 - 0.12$	$V_{DDQ}/2 + 0.12$	V	1, 3
Output Low Voltage	$V_{OL1}$	$V_{DDQ}/2 - 0.12$	$V_{DDQ}/2 + 0.12$	V	2, 3
Output High Voltage	$V_{OH2}$	$V_{DDQ} - 0.2$	—	V	4, 5
Output Low Voltage	$V_{OL2}$	—	0.2	V	4, 6

**Notes:**

- $I_{OH} = (V_{DDQ}/2) / (RQ/5) \pm 15\%$  @  $V_{OH} = V_{DDQ}/2$  (for:  $175\Omega \leq RQ \leq 275\Omega$ ).
- $I_{OL} = (V_{DDQ}/2) / (RQ/5) \pm 15\%$  @  $V_{OL} = V_{DDQ}/2$  (for:  $175\Omega \leq RQ \leq 275\Omega$ ).
- Parameter tested with  $RQ = 250\Omega$  and  $V_{DDQ} = 1.5\text{ V}$
- $0\Omega \leq RQ \leq \infty\Omega$
- $I_{OH} = -1.0\text{ mA}$
- $I_{OL} = 1.0\text{ mA}$
